

Comparaison de LOF, OC-SVM et Isolation Forest

Jeux de données

Nous utilisons deux jeux de données Shuttle et KDD-Cup99 HTTP

Algorithmes comparées

Nous comparons LOF, OC-SVM et Isolation Forest qui sont des méthodes non supervisées de détection d'anomalies Pour chacune de ces méthodes,

- Nous utilisons l'implémentation faite par scikit-learn
- Nous les initialisons avec les valeurs par défaut
- Pour chaque méthode, nous faisons varier un paramètre et exécutons la méthode sur le jeu de données un certain nombre (x) de fois.
- La moyenne des x temps d'exécution et de AUC donne la valeur à considérer pour cette valeur de paramètre concernant cette méthode.
 - Isolation Forest : Contamination (0 à 0,5 pas de 0,1) ----Plutôt faire varier n_estimators (50 à 300 pas de 10)----
 - OC-SVM : nu (0,1 à 1 pas de 0,1) comme dans Goldein et Uchida
 - LOF : n_neighbors (5 à 200 pas de 5) comme dans Goldein et Uchida
- Ceci permet de connaître pour chaque algorithme la valeur du paramètre le plus important qui permet d'avoir le meilleur résultat.
- La courbe ROC sera alors dessinée pour toutes les méthodes ensemble en utilisant leur meilleur paramètres.
- Un tableau sera fait pour comparer le temps d'exécution moyen, la précision moyenne, la AUC moyenne, le rappel moyen des méthodes sur chaque jeu de données.
- Les interprétations seront données pour chaque méthode à propos de chaque jeu de données et pour tous les jeux de données par la suite.

NB: On ne peut pas dessiner la courbe des AUCs comme dans Goldein et Uchida parce que les méthodes qu'ils ont comparé ont des paramètres en commun notamment les méthodes basées sur les plus proche voisins. Ce qui fait qu'ils ont pu tracer la courbe des AUCs en faisant varier le nombre de voisins et comparer les performances des méthodes entre elle. Dans notre cas, ces trois méthodes n'ont rien en commun pour un tel exercice.

Métriques de comparaison

Nous comparons ces méthodes sur la base du temps d'exécution et sur la base de l'air sous la courbe ROC (ROC AUC)

- Nous calculons le temps d'exécution de la fonction sur ces jeux de données avec la fonction time() que nous appelons avant de lancer l'initialisation de la méthode pour avoir l'heure de début. Nous appelons encore la fonction time() à la fin de l'exécution de la fonction predict() de la méthode pour avoir l'heure

de fin du traitement. La différence entre ces deux moments nous donne le temps d'exécution de la méthode en secondes (s)

- Nous calculons l'aire sous la courbe ROC avec la fonction `roc_auc_score()` de `scikit-learn`
- La précision
- Le rappel
- Le score f1
- la courbe ROC ##### Temps d'exécution Le temps d'exécution est le temps qui sépare le lancement de la méthode à la fin de sa prédiction. Ceci permettra d'évaluer les différentes méthodes en fonction de temps qu'elles prennent pour classer les observations dans le dataset en anomalies ou normales. Il sera tenu compte du fait que le temps d'exécution peut être fonction du type du jeu de données de la taille du jeu de données et du nombre de dimension. ##### Précision ()

$$TP / (TP + FP)$$

Le taux d'observations classées positives (ici normale) par la méthode par rapport à toutes les observations réellement normales ##### Rappel (TPR)

$$TP / (TP + FN)$$

C'est le taux d'observations positives (ici normale) ayant été correctement détectées par la méthode. ##### Score f1

$$TP / (TP + (FN + FP) / 2)$$

F1 est la moyenne harmonique de la précision et du rappel. F1 donne plus de poids aux faibles valeurs et est donc utile pour comparer deux méthodes de classification

Courbe ROC

O = Outlier = Négatif N = Normal = Positif

O | N

O | VN | FP

N | FN | VP

ROC AUC

La valeur max est 0.9530882878060613 à l'index 2

Interprétation du résultat de IsolationForest sur Shuttle

Le temps d'exécution de IForest n'est pas lié à la variation de contamination (le taux d'anomalies dans le jeu de données). Par contre en ce qui concerne l'aire sous la courbe ROC, la meilleure performance est arrivée quand contamination est à 0,1. 0,1 est d'ailleurs la valeur par défaut de contamination au niveau de scikit-learn. Conclusion: Refaire l'exercice en faisant varier cette fois-ci `n_estimators` (le nombre d'estimateurs de l'ensemble à utiliser pour tester l'aberrance des observations).

Avec `n_estimators` entre 50 et 300, on remarque que le temps d'exécution augmente au fur et à mesure que le nombre d'estimateurs augmente. Concernant la performance, la meilleure estimation a été obtenue pour un taux de AUC = 0.9530882878060613 avec `n_estimators = 70` ==> (50+2*10) A noter que quelque soit la valeur de `n_estimators`, la AUC est toujours supérieure à 0,95

Interprétation du résultat de OC-SVM sur Shuttle

Plus la valeur de ν augmente plus le temps d'exécution diminue. OC-SVM est donc plus rapide sur Shuttle avec un ν plus grand. Mais, cela n'entraîne pas un bon résultat de la méthode. Puisqu'à partir d'un ν de 0.5, la prédiction de l'algorithme devient de plus en plus aléatoire. La meilleure performance est atteinte à $\nu = 0.4$

Interprétation du résultat de LOF sur Shuttle

Plus le nombre de `n_neighbors` augmente, plus de temps d'exécution est important. Ceci s'explique par le fait que plus le nombre de voisins à considérer est grand plus il faudra calculer les distances et les densité afin d'estimer le degré d'aberrance d'une observation. Concernant la performance de la méthode, elle atteint son plus fort ($AUC = 0.6455513956598792$) à taux à `n_estimators= 80` ($((15+1)*5)$) pour un temps d'exécution de 22.768262100219726

Interprétation des résultats en fonction du Temps d'exécution, précision, rappel, score f1, AUC sur Shuttle

IsolationForest a eu de meilleures performances que les autres. Entre OC-SVM et LOF : OC-SVM a découvert et bien classé plus d'anomalies que LOF. Par contre, LOF a découvert et bien placé plus d'observations normales que OC-SVM. La question est donc de savoir ce qui importe le plus entre la découverte des anomalies et celle des observations normales car c'est en fonction de l'importance que nous donnons à l'un ou à l'autre que nous pourront dire la méthode la meilleure entre OC-SVM et LOF. Cette question fait remarquer qu'en réalité, toutes les méthodes ont sont performantes dans des conditions données en fonction de ce que l'on souhaite obtenir comme résultat. Dans ce cas précis, OC-SVM lance beaucoup de fausse alertes mais attrappe beaucoup d'anomalies. Par contre, LOF n'attrappe pas beaucoup d'anomalies mais reconnais beaucoup de données normales. On peut peut-être se dire que dans le cas espèce OC-SVM est mieux dans la mesure où une méthode de détection d'anomalies a pour but principal de détecter les anomalies et donc laisser passer des anomalies en ferait une méthode moins bonne et que les observations normales que OC-SVM aurait classé comme anormales sont peut être des nouveautés. Considérant l'aire sous la courbe ROC, nous avons l'ordre suivant IForest - OC-SVM et LOF

Tableau du résultat $TOBC = VN/(VN + FP)$ $TNBC = VP/(FN + VP)$

Méthode	Précision	Rappel	Score f1	AUC	TOBC	TNBC	CPU Time
IForest	0.9997608	0.9084148	0.9566490	0.9528561	0.9886105	0.9171017	2.5428619
OC-SVM	0.9982955	0.6038696	0.7525321	0.7751694	0.9464692	0.6038696	176.90205
LOF	0.9870808	0.9171017	0.9461154	0.6455514	0.3826879	0.9084149	24.813836

plt.legend(loc="lower right")

plt.show()
```

Interprétation de la courbe ROC

La courbe ROC mesurant le taux de faux positif par rapport au taux de vrai positif, plus la courbe s'éloigne de celle oblique en noir, mieux c'est. Ainsi, on peut dire que pour Shuttle, IForest est la meilleure méthode de détection d'anomalies suivi par OC-SVM. Le classement de LOF pourrait s'expliquer par le fait que les anomalies qui y sont présentes sont des anomalies global alors que LOF est doué pour les anomalies locales. POur vérifier ça peut être qu'on peut utiliser une méthode de clustering comme K-means pour voir comment les anomalies seront classées par cette méthode.

Conclusion Shuttle

Pour un jeu de données statique de faible dimension, Isolation forest a tendance à mieux performer et semble être plus rapide que OC-SVM et LOF. OC-SVM détecte beaucoup d'anomalies avec un fort taux de fausses alertes et un temps d'exécution plus grand que LOF. Par contre, LOF détecte moins d'anomalies avec un faible taux de fausses alertes. Notons que la performance des méthodes dépends non seulement du jeu de données considéré mais aussi des valeurs des hypermaramètres. Pour LOF et IsolationForest, le temps d'exécution semble être en corrélation positive avec respectivement le nombre de voisins et nombre de d'estimateurs. Par contre, le temps d'exécution serait en corrélation négative avec nu.
